Simulations of an Ar/HBr/O₂ microwave source etch process and the effect of SiBr and SiBr₂ cross-sections on computed etch-profiles

JAMES MUNRO, JONATHAN TENNYSON, University College London, SONG-YUN KANG, Tokyo Electron Limited, DANIEL BROWN, Quantemol Ltd. — Electron–molecule scattering calculations are performed for SiBr and SiBr₂ using Quantemol-N.¹ These cross-sections are then used to construct a set gas phase reactions for the plasma simulation. An etch-profile simulation is then performed using the Monte Carlo Feature Profile Model (MCFPM)² with inputs supplied by simulation of an Ar/HBr/O₂ plasma. Computed cross-sections include the total elastic cross-section, dissociative electron impact cross-sections, ionisation cross-sections and an estimate of the dissociative attachment cross-section. The use of Ar/HBr/O₂ chemistries have been studied previously^{3,4} and a reduction in microtrenching was found when HBr was included. An analysis of the contribution of SiBr and SiBr₂ to the computed etch profile will be presented at the conference.
