Modeling the statistics of elementary calcium release events¹

GHANIM ULLAH, PETER JUNG, Ohio University — Elementary Ca^{2+} signals, such as ' Ca^{2+} puffs', which arise from the release of Ca^{2+} from Endoplasmic Reticulum through small clusters of inositol 1,4,5-trisphosphate receptors, are the building blocks for intracellular Ca^{2+} - signaling. The small number of release channels involved during a Ca^{2+} puff renders the puffs stochastic with distributed amplitudes, durations and frequency, well characterized experimentally. We present a stochastic model that accurately describes simultaneously the statistical properties of the duration, amplitudes, frequencies, and spatial spread with a single set of parameters.
