the American Physical Society

**Phase diagram of the 2D frustrated quantum magnet  $\text{Cs}_2\text{CuCl}_4$  in applied field**

RADU COLDEA, University of Bristol, UK

We use neutron scattering, magnetization and specific heat to probe how the ground state of the 2D spin-1/2 anisotropic triangular lattice antiferromagnet  $\text{Cs}_2\text{CuCl}_4$  evolves as a function of applied magnetic field. We observe that the zero-field incommensurate spin spiral is suppressed by relatively small in-plane fields giving way to a commensurate 2D antiferromagnetic pattern stable over most of the intermediate field region, with incommensurate order appearing again for a narrow field range just below ferromagnetic saturation. The commensurate phase is not captured by a classical mean-field approach, suggesting that quantum fluctuations may be important in stabilizing this type of order.
