Spin-dependent band structure of the ferromagnetic semimetal EuB_6 PENG XIONG, X. ZHANG, S. VON MOLNAR, Florida State University, Z. FISK, University of California at Irvine — The spin polarization of EuB_6 crystals has been measured using Andreev reflection spectroscopy. The conductance spectra of the EuB_6/Pb junctions are well-described by the spin-polarized BTK model, which yields a spin polarization of about 56%. The results demonstrate that ferromagnetic EuB_6 is not half-metallic. Further analyses of the Hall effect and magnetoresistivity indicate a semi-metallic band structure with complete spin polarization for the hole band only. The values and the spread of the measured spin polarization are *quantitatively* consistent with Fermi surface determined by quantum oscillation measurements¹ and carrier densities obtained from standard two-band model fits to the low temperature magnetoresistivity and Hall resistivity.
