Abstract for an Invited Paper
for the MAR10 Meeting of
the American Physical Society

Scanning Tunneling Microscopy and Spectroscopy of Iron-Based Superconductors¹

JENNIFER HOFFMAN, Harvard University

Two decades after the discovery of high- T_c superconductivity in the cuprates, superconductivity was discovered up to 55 K in a second family of materials: the iron-pnictides. This recent discovery has generated tremendous excitement for several reasons. First, there is hope that the iron-pnictides will finally provide the foil necessary to understand the enormous yet puzzling body of research on the cuprates. Second, reports of low anisotropy and strong vortex pinning in these new materials have spurred optimism that the iron-pnictides may finally lead to the widespread technological applications which have been elusive for cuprates. In this talk, I will present the first scanning tunneling spectroscopic imaging study of a single crystal iron-pnictide superconductor in high magnetic fields. We study optimally doped $\text{BaCo}_{0.2}\text{Fe}_{1.8}\text{As}_2$ with $T_c = 25.3$ K, finding a ~ 6 meV superconducting gap with nanoscale inhomogeneity, which leads to an average reduced gap of $2\Delta/k_B T_c \sim 5.7$. We further observe a static disordered vortex lattice at 9 T, and demonstrate that vortices are pinned in the bulk of this material, a promising observation for practical application.
