Ag/Al₂O₃/FeAl(110): Electronic structure and NO₂ adsorption

MATTHEW PATTERSON, Department of Physics and Astronomy, Louisiana State University, ORHAN KIZILKAYA, Center for Advanced Microstructures and Devices, Louisiana State University, RICHARD KURTZ, PHILLIP SPRUNGER, Department of Physics and Astronomy and Center for Advanced Microstructures and Devices, Louisiana State University — Ag/Al₂O₃ systems are widely studied as catalysts in the selective catalytic reduction of NO_x with hydrocarbons. The exact nature of the active sites and the role of the Ag clusters in such reactions is still not fully understood. In this study, we characterize thermally evaporated Ag clusters on the ultrathin alumina film produced by oxidizing FeAl(110). ARPES demonstrates the evolution of Ag cluster electronic structure and morphology with increasing Ag coverage. Changes in electronic binding energy distinguish charged from metallic clusters. Vibrational EELS of NO₂ adsorbed on the Ag/Al₂O₃/FeAl(110) system elucidates the nature of the NO_x binding site and the changes in the surface chemistry both as a function of Ag cluster size and NO_x adsorption temperature.
