Simulating electron spin entanglement in a double quantum dot¹

M.A. RODRIGUEZ-MORENO, A.D. HERNANDEZ DE LA LUZ, Centro de Investigaciones en Dispositivos Semiconductores, Instituto de Ciencias BUAP, LILIA MEZA-MONTES, Instituto de Fisica BUAP — One of the biggest advantages of having a working quantum-computing device when compared with a classical one, is the exponential speedup of calculations. This exponential increase is based on the ability of a quantum system to create and operate on entangled states. In order to study theoretically the entanglement between two electron spins, we simulate the dynamics of two electron spins in an electrostatically-defined double quantum dot with a finite barrier height between the dots. Electrons are initially confined to separated quantum dots. Barrier height is varied and the spin entanglement as a function of this variation is investigated. The evolution of the system is simulated by using a numerical approach for solving the time-dependent Schrödinger equation for two particles.
