Development of Graphene for High Frequency Electronics

JOSHUA ROBINSON, The Pennsylvania State University, DAVID SNYDER, MARK FANTON, MATTHEW HOLLANDER, MICHAEL LABELLA, KATHLEEN TRUMBULL, RANDALL CAVALERO, BRIAN WEILAND, THE PENNSYLVANIA STATE UNIVERSITY TEAM — The practicality and success of a graphene technology depends on the ability to regularly and controllably synthesize graphene; integrate it with metals and dielectrics; and to develop device designs that take advantage of graphene's unique properties. We demonstrate graphene synthesis on SiC(0001) and Sapphire with 1.5% variation in sheet resistance across 100mm wafers. Hall mobility measurements indicate that direct growth of graphene on sapphire leads to a 2x increase in mobility ($2200 \text{ cm}^2/\text{Vs}$) compared to silicon sublimation from SiC(0001). Additionally, we have developed high quality ohmic contacts to graphene, which improves the contact resistance by nearly 6000x ($5 \times 10^{-8} \text{ Ohm-cm}^2$) compared to untreated metal/graphene interfaces. Finally, we discuss integration of ultra-thin high-k dielectrics and their impact on graphene transport. Atomic layer deposited oxide heterostructures (seed not equal to overlayer) have deleterious effects on Hall mobility while homostructures lead to an increase in Hall mobility. Importantly, 5nm thick EBPVD HfO_2 gate dielectrics are successfully demonstrated and show improved Hall mobility, on-off ratio, and transconductance relative to Al_2O_3 gates and heterostructure gates.
