Out-of-Equilibrium Transport near a Quantum Phase Transition

STEFAN KIRCHNER, Rice University, Houston, LIJUN ZHU, University of California, Riverside, QIMIAO SI, Rice University, Houston — Non-equilibrium properties are expected to be particularly rich at a second order quantum phase transition, given that statics and (imaginary time) dynamics are already mixed at the equilibrium level. The issue has so far received only limited study, partly because equilibrium methods are not readily generalizable to non-equilibrium situations. Here we consider the quantum critical point of a Bose-Fermi Kondo model, which we have recently shown\cite{1} to model the magnetic quantum dot systems\cite{2}. We extend the saddle-point equations in a dynamical large-N limit\cite{3} to the Keldysh contours, and determine the linear and non-linear conductance in the quantum critical regime. \[1\] S.
